

## DOCUMENTATION – Problems I've Faced/Solutions

## Overall Game Play:

- Problem- At first I tried to do one big composable function for the game play, but then I started mixing the UI with too much logic
- Solution- I split it up into 3 categories: GameState, GameController, then the GameScreen. So I made an entity, controller and a 'boundary' (Composable) object

## Game Play State Object:

- Problem- I made an object of this inside the GameScreen, so it was mutable, however, I noticed the composable only tracks the overall object not the contents within it
- Solution- I had to explicitly make the variables "by mutableStateOf" or something similar because that notifies the composable if it actually changes

## Changing Screens:

- Problem- I had multiple screen I had to change to, and it was getting harder to track to which screen appears or not
- Solution- I should've probably made a ScreenController class and then change it from there, BUT I just simply used a currentScreen variable within the compose and then a "when" to change screens
